Replacing its Mobile Fusion brand, BlackBerry has launched its BlackBerry Enterprise Service 10 which is now available for download for businesses

Evolving digital frontiers

Changes are constant and adaptation is the name of the game as the Internet grows in size and complexity

A part from regular updates from the usual players, we've had reason to celebrate, as the Internet turned 30 in January, beginning to mature into a more evolved entity. It is still finding its feet under the frenetic mass of ever-burgeoning social media interaction however, whilst withstanding the onslaught of censorship policies and cyber-attacks at the same time.

The Internet found its beginnings as Advanced Research Projects Agency Network (ARPANET) when it switched over from using Network Control Protocol to TCP/IP (Transmission Control Protocol/ Internet Protocol). History notes that this change was not easy, as many operators resisted going from an already working system to something that was just a "standard" in text. It is said that one day, the admins of ARPANET just flipped the switch, turning off all of NCP for a day or so to get people to switch over to TCP/IP.

With those humble beginnings, the Internet has grown into an entity that is now an integral part of everyone's lives. While it may be entirely possible to live a day or two without the internet, it is hard to imagine a life without it.

Facebook unveils Graph Search

Facebook in January announced a new search engine on its social networking web site, making search results more relevant to you on a social scale. Data accu-

mulated from user profiles over the years make results closer to you and your friend's circle.

Launched in the beta version at the moment, Graph Search is available to limited users, and will be rolled out slowly across the board. The Graph Search results focus on four core points – people, places, photos and interests. Facebook can easily create these results after it spent quite a few years urging users to upload information, interests and photographs to their profile online. The premise of people search works on both types of queries

– direct and general. An direct people search example given by Facebook is "people named Chris who are friends of Lars and went to Stanford". Alternatively, you could do a generic search like "My Friends who live in New Delhi".

Apart from direct people related search, you could search for interests that you may have. There are examples like "music my friends like" or "my friends who watch BBC Top Gear". This is not something that Google had claimed to do till now, but should rather start doing with the Google+ network.

Apart from the people search, the photo search is surely going to see the privacy brigade go up in arms. Search phrases such as "photos of friends at Hard Rock Café" or a more precise "Disha's photos in Paris". With this, Google must be worried. Photographs uploaded on Facebook will be found on Facebook, like they always have been. With Graph Search, the process is more varied in terms of how you search and more streamlined in terms of the results that you get.

With location search, if you happen to be travelling to a city you do not know a lot about, you could search for "bars in Liverpool liked by people who live in Liverpool". This is something that could worry the likes of Foursquare and TripAdvisor, because localised ratings, reviews and knowledge about places is what they bank on.

Interestingly, Facebook has tied up with Microsoft to

provide Bing search results for the queries it may not have answers to.

Heavily cloud connected?

While announcing the new Graph Search feature, Facebook revealed its users have uploaded staggering 240 billion photos and created 1 trillion connections on the network to date. On an average, a normal Facebook user would have uploaded more than 200 pics and made a thousand connections. The staggering feat comes months after Facebook announced in October that the company had gone past the 1 billion active users mark. The social networking as a service is also now believed to be the most popular online ever.

Like who?

A recent study (by the University of Warwick and UC San Diego) has shown that people remember posts that they have seen on Facebook a lot easier than they do names, faces, or even information they read in a book. The study suggests the gossipy nature of the conversations that happen on the social networking web site make it easier to remember than something that is written in a more formal and informative manner. "One could view the past five
