

Doodle 4 Google

The yearly competition which invites young students to design Google's homepage is now open for US. <http://dgit.in/W3M84d>

Intex's New Aqua

The budget Android market has seen the launch of two new dual-SIM Android devices; Intex Aqua Flash and Trendy <http://dgit.in/100a01G>

Cabinets Test

HOW WE TESTED

The cabinets we received for this test spanned across categories. There were mini-towers, mid-towers and full-towers of all shapes, so we decided to divide the mini-tower and mid-tower cabinets according to their price range, namely cabinets below ₹5,000, cabinets between ₹5,001 to ₹10,000, and cabinets above ₹10,001. For the last category we grouped full-tower cabinets together.

TEST RIG (For mid-towers and full-towers):

Processor: AMD Phenom II x4 955 Black Edition with stock cooler

Motherboard: Gigabyte MA790FXT-UD5P

RAM: Kingston HyperX 8GB DDR3-2133

Graphics Card: ATI Radeon 4870x2

Power Supply: Cooler Master Silent Pro 850 Watts

Hard Disk Drive: Seagate Barracuda 80 Gb SATA

Operating System: Windows 7 Ultimate

TEST RIG (For mini-towers):

Motherboard: ECS Elitegroup A785GM-M

Black Series Except the motherboard, all other components used for testing mini-towers were the same.

We assigned 50 percent weightage to the cabinet features, 40 percent to performance and 10 percent weightage for included accessories. We also took a note of the location of the power and reset buttons, the location of audio jacks and PSU placement. Cabinets which provided features for better cable management, dust protection and tool-less design were awarded more points.

For testing the performance of the cabinets, we calculated the difference between the load CPU and GPU temperature and cabinet's internal temperature when idle. We used Cinebench R11.5 to stress test the CPU by running three loops of the CPU benchmark and took a note of the hottest CPU core using core temp in the final loop. The ambient temperature and case internal temperature was measured using a digital thermometer. We chose to use the ATI Radeon HD4870x2 as our test GPU because it runs extremely hot

even when it's idle and obviously on full load. For stressing the GPU, we ran the OpenGL benchmark for two loops in Cinebench R11.5, which put the GPU under 100 percent load, we then used GPU-Z and MSI Afterburner to get the idle as well as load temperatures of the GPU during testing.

We kept the temperature probe of the digital thermometer suspended right between the CPU and GPU area which allowed it to capture the most accurate case internal temperature. Cable management was perfectly observed for every cabinet so that wires didn't block the air-intake as well as exhaust. All of the unused as well as the in-use wires were tied using wire strings.

The fans included with the cabinets were allowed to run at their full speed (even for the cabinets which had a fan controller pre-installed). The orientation and placement of included fans was not disturbed or changed, so the included fans were placed at their default places during the test; this practice dismissed unfair advantage (if any) for every cabinet.
