

Next Xbox: Always on

A leak claims that Microsoft's next Xbox gaming console, codenamed Durango will always need to be connected in order to play games

Custom built smartphones?

According to a Motorola advisor, it may be possible that Motorola will release custom-built Android handsets in the near future. The X-phone is also believed to be a part of this

Tomorrow's Tech

to deal with the booming population while delivering toys to every child, ever – improbable, but makes for an interesting conversation. In some ways, the maglev concept has been pretty unlucky as well – because it is a new incarnation of an old concept (trains), and it messes with our existing infrastructure so much that we, in our impeccably true human style, seem to have given it the cold shoulder. All the engineering challenges have been conquered, but the question of freakishly high maintenance costs are too high to be really of any degree of widespread use. Too bad.

VacTrains

Now these are true hallmarks of a promising future. It's amazing that although they are not that different from the maglev concept, they are still in with a bigger shout than most to be the mainstay of modern transportation systems. The central idea is that there will be air-sealed

And to think that beasts like this run on some corner of the face of the Earth.
#secondworldproblems

tunnels laid out and about, and the wagons will be controlled in this pseudo-vacuum environment, with concepts of superconduction thrown in for good measure. Of course, the challenges to create and maintain the levels of perfection that the system would seemingly require are huge, but initial estimates ascertain that once we're through with actually creating something along these

lines, it would probably be pretty cheap (and drastically fuel-efficient over most other suggested methods of transportation) to keep it going. And because most of the work is being done by air, we would probably have it easy in terms of resources and environmental friendliness. Win-win! Oh, and did we mention the possible speeds of 6,500 kmph? Win-win-win.

Personal rapid transit

If it were to ever come down to us to choose the one system that we like best, it would be this one. It is essentially a taxi service that will take you anywhere you want to go (system permitting, of course). The idea is to gather 6-10 people who are going to nearby places, into a pod, and drive them there. Interesting variations being the driverless implementation, and the 'follow-the-leader' system, wherein the pods run like compartments of a train, one behind the other, and then break from the chain when they reach the appropriate closest
