

ThinkPad design worsening

A report on how ThinkPad's design decisions are slowly but surely not making any sense. Do you agree with the view? <http://digit.in/13hoj0G>

App for LazyHusband

A 12-yr-old developer unveiled an app that compliments women at the touch of a button <http://digit.in/11nEa96>

Q&A

under warranty, and the firmware update doesn't work, try claiming warranty. Do all the devices on your network use 802.11g? If so, try switching the router to run in g mode only. If all of them are N capable, switch to 802.11n.

If you have a lot of Wi-Fi interference around you (many networks showing up when you search for Wi-Fi connections in your device settings), try changing the broadcast channel.

Migrating stuff

I am a BlackBerry user and have just switched to Android OS. I purchased a Google Nexus 4 and I am having issues syncing my Outlook calendar with my Google calendar. That was not the case with my older BlackBerry phone. I see some entries while others are not visible. Also all my calendar notifications are set to London time although my phone time is showing the Indian time zone. How do i get rid of that issue?

Kanak

Let us start with your second issue first. To change the London time, you need go to Settings > Date and Time. Now your Automatic Date and Time setting must be set to network provided time but your time zone will still be showing as GMT +0.00. Make that GMT +5.30 Kolkata so all your calendar appointments will be set according to the Indian time zone.

For the second issue, you need to download a utility called Google Calendar Sync (<http://goo.gl/L2pYb>) and install it on your system. While installation it will ask you for your email ID which you are using your Nexus 4 with, enter those credentials. It will then ask if you want to do a 2-way sync (Google Calendar and Outlook entries will be synced simultaneously) or 1-way sync (either Outlook to Google Calendar or vice versa). We suggest you do the 2-way sync, that way both your Outlook and Google Calendar will be up to date. You can also decide how often you want to sync by entering the number of minutes in the box below the sync options.

Overclocking the GPU

I have bought an ASUS GTX 650Ti graphic card. I have a B75M D3H motherboard,

Core i5-3450 processor and 4GB Kingston RAM. The card works fine, but when I overclock it using GPU TWEAK then the screen flashes and I see blue stripes and then the screen flashes again and says that NVIDIA 314.14 video driver stopped responding and successfully recovered. My card has a default GPU clock of 928MHz and shows that it is overclockable up to a maximum of 1278MHz. But I am not able to do so. Please guide me.

Sourish Banerjee

It seems like your card is not able to keep up with the overclock you are subjecting it to. Overclocking is a trial and error process and it also depends on the temperature of the card. Maybe you are overclocking it to an extent where the GPU load temperature is going beyond the threshold and restarting the system hence giving you the blue screen. After every overclock make sure you run a benchmark like 3D Mark 11 to ensure that the overclock is stable and under control.

Also try using a stable driver such as the 314.07. The one you are using 314.14 is currently a beta driver and you may face issues with it. There have been reports of random crashing of games with those users using the 314.14 driver.

Usable RAM vs actual RAM

I have recently bought a system with the following configuration:

- Processor: Intel Core i5 3450
- Motherboard: Gigabyte Z77M-D3H
- Ram: 8 GB Corsair Vengeance 1600 Mhz
- HDD: Seagate 1 TB 7200 RPM
- Cabinet: Cooler Master Elite 430 Black
- PSU: Cooler Master 625W Extreme
- Graphics Card: XFX Radeon 7770 1 GB
- OS: Windows 7 Ultimate 32 bit edition

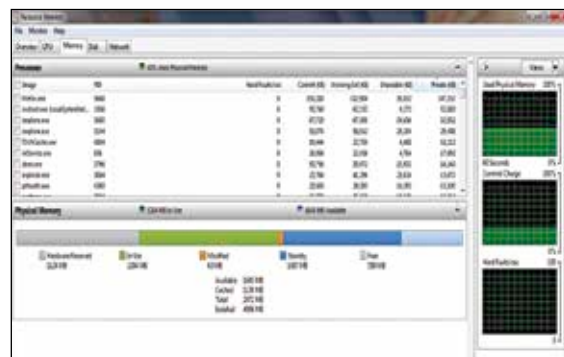

I am facing some problems with my system. I want you to solve this for me.

Firstly, When I open the system properties by right clicking My Computer icon it shows that only 3.48GB RAM is in use, but it also shows that 8 GB RAM is present. I tried disabling the onboard VGA in the

BIOS but with no result. Does Windows 7 Ultimate 32 bit Edition not support 8GB RAM? But then why is it not showing total 4GB in use? What's wrong? Secondly, though the RAM frequency is 1600 MHz it shows only 1333 MHz in the BIOS when system starts. It can be increased to 1600 MHz in the BIOS but why is it running at a lower speed than specified because the motherboard supports 1600 MHz memory speed? Lastly, please suggest about the system. Is it OK for moderate gaming and multimedia tasks like watching high-end videos and video transcoding?

Amal Bhattacharya

Microsoft Windows 32-bit OS only supports upto 4GB of RAM. It will not recognise anything over 4GB. Go to Start

Resource Monitor screen

> Resource Monitor > Memory tab. Here you will get an idea where the remainder of the memory is being used. Most of the time some memory will be reserved for hardware. If you intend to use the complete 4GB, then go to Start > Run > msconfig > Boot tab > Advanced options. Make sure that Number of Processors and Maximum memory are unticked. Click Apply.

The memory is rated at 1600MHz, which means that you can run it at that speed. Generally it runs at a lower clock so as to keep the system stable. You can change the frequency in BIOS Frequency settings but make sure you give the correct RAM timings as well.

Your system is quite good for all the tasks that you have mentioned such as gaming, transcoding and watching HD videos should run without any hitch.
