

Move the image to the next mark and scan without altering the settings. Save this file as image2.tif. Repeat the process till you have scanned the entire image. To scan the lower half of the image, turn the painting by 180° and repeat the above process. This time use a different naming convention like lower1.tif, lower2.tif. This is necessary because we will have to flip these lower images before creating the final image.

Open all the images in Photoshop. Create layers for each image by clicking **Layer > New > Layer from Background**. Rotate the canvas by clicking **Image > Rotate Canvas > 180°** for all the lower-half images. Create a new blank image, large enough to accommodate all these images. Put all the layers on this image and align them appropriately to get the final picture. You can also use Photoshop CS's (Creative Suite) Photomerge feature to automate the last step.

Saving Scanned Images

Save images scanned to be used on the Web or be sent as e-mail attachments in the .JPEG format. . GIF is a better option for images such as line arts that have less than 256 colours since it results in smaller file sizes.

If you plan to edit the images later, save them in an uncompressed format. You may also save them in the TIF format as it allows compressing without causing loss of image quality. If you are scanning images for archival, it's always recommended that you save one copy in your image editor's native format. For example, if you use Photoshop, save a copy in the PSD format. You might want to save the second copy in high quality JPEG format.
