

but with MMS, a virus can send itself across the world—as is the case of CommWarrior.a. Just like a worm on your PC, CommWarrior scans the phone's address book and periodically sends MMS messages to randomly selected con-

tacts. It sends a copy of itself and one of several predefined text messages designed to encourage the recipient to install the application. The good thing is that the application is still only installed by your choice.

There are many other things besides viruses that are considered a nuisance by smartphone users, all related to Bluetooth. A few of these are as listed below:

Bluejacking: Although known to the technical community and early adopters for some time, the process now known as 'Bluejacking' has recently come to focus in the consumer arena, and is becoming a popular mechanism for exchanging anonymous messages in public places. The technique involves abusing the Bluetooth 'pairing' protocol, the system by which Bluetooth devices authenticate each other, to pass a message during the initial 'handshake' phase. This is possible because the 'name' of the initiating Bluetooth device is displayed on the target device as part of the handshake exchange. As the protocol allows a large user defined name field—up to 248 characters—the field itself can be used to pass the message.

SNARF Attacking: It is possible, on some mobile phones, to connect via Bluetooth without alerting the owner of the phone. The person connecting to the target phone gains access to the phonebook, messages and other important data. This is normally only possible if the device is in 'discoverable' or 'visible' mode, but there are tools available on the Internet that allow even this safety Net to be bypassed.
