

where members have begun to date one another. There is no confusion in the use of the site where the border of use for the network is more defined.

We are seeing a shift towards the Semantic Web as a Web of relationships evolves towards a metaweb that is one towards a Web of relationships. With the rise of the social and business networks online we are seeing the growth in the number of connections and relationships. The connections between people and their links and the valuable contribution to one another in learning and providing a number of positive links across a network. The next generation communities will evolve as a mixture of humans and intelligent software forming knowledge networks that will enable a type of distributed intelligence across the internet amongst communities, individuals and social and business networks. There will be the evolution of these types of sites also with the auto-creation or nomination of RDF assertions about individuals based on the user profiles. There will also be the emergence of the social networks for knowledge collection, collaboration and dissemination. There will be a people search based on the most connected individuals or those most connected with you.

The role of the User profiles in these networks will steadily increase in value as these networks take a shortcut through the sea of persons out there on the web to show the value of these connections based on the relationships people have with one another.
