

Data transfer using Circuit Switching - all packets follow the same path to their destination

say, “keeps my data from going AWOL.” True, circuit switching is good, especially for voice transmissions.

But there’s a catch; this path remains reserved even if no data is being sent - an unfortunate waste of a perfectly good connection. An alternative to this was to send packets on all the possible paths to the receiver. Just tag the packet with the name of its destination and its place in the sequence of packets and send it off on its journey. The receiver would receive these packets, put them in the right order and *voila!* - ready-to-use data. This technique is

Data transfer using packet switching - the grey packets use different possible paths to get to their destination. At the end, they are arranged in the proper sequence and then used.
