

Solution/Workaround: To rectify the first problem, all you have to do is relocate the virtual memory to another partition. Let's assume the system has 256 MB of RAM; the virtual memory should ideally be 1.5 times the RAM, that is, 384 MB. But this value may be insufficient if Windows XP is installed running many memory-hungry applications. So, take three times the size of RAM if the system RAM is less than or equal to 256 MB. The safe value in our example would be 768 MB.

To administer these changes, go to **Control Panel > System**. Find "Virtual Memory" and click on it to change the settings. For Windows XP users, virtual memory is located under the 'Advanced' tab of the

System Properties dialog box that pops up on double-clicking 'System' in the Control Panel. Click on the 'Change' button to change the size of the virtual memory. Choose an initial size and final size for the page file. You can also choose to change the partition under which the page file should reside. Set the values and apply the changes. You will have to reboot the machine to effect the changes.

RD RAM

RD RAM should be installed in pairs and the open slots should be filled with Dummy modules else machine will not boot due to RAM error
