Resolution simply defines the number of pixels per line horizontally, called Width, and the number of pixels vertically, called Height. For Example, a resolution of 800x600 means there are 800 pixels row-wise and 600 pixels column-wise.

In the illustration below, we have a resolution of 28 x 21. Note that the ratio is 4:3. In the darkened area, you will find 5 x 5 pixels. Assuming that this area is 1 inch x 1 inch, the dpi will be $5 \times 5 = 25$. In an actual image, the numbers will be much larger, but the concept remains the same.

2.2.1 DPI (Dots Per Inch)

When we say there are 800 pixels making up a line horizontally, it is only an absolute value of pixels. But it does not define how big the image physically is (in terms of inches or centimetres). If you wish to print an image, the resolution by itself does not tell you how big or small your print is going to be. The physical size is calculated from the resolution using another value called the dpi or *dots per inch* (it can also be dots per centimetre or anything else.) As the name suggests, it defines the number of dots that compose a
