

Here's an example:

```
<html>
<body>
Welcome <?php echo $_POST["name"]; ?>.<br />
You are <?php echo $_POST["age"]; ?> years old!
</body>
</html>
```

We've created a .php file with the above code. If you attempt to execute this file, however, you'll get an error simply because the variables haven't been assigned any values. We now create another .php file, with the code as given below.

```
<html>
<body>
<form action="formhandling.php" method="POST">
Enter your name: <input type="text"
name="name" />
Enter your age: <input type="text" name="age"
/>
<input type="submit" />
</form>
</body>
</html>
```

This code actually redirects to the file mentioned (in this case "formhandling.php"), passing on the values for "name" and "age", and uses these values with the output statements given in the previous script.

In the next chapter we'll focus on site design tools, a far cry from PHP scripting, but nonetheless a necessary part of Web site integration and design.

A simple page with values passed from another PHP script
