

On the calculus side, Geogebra can find derivatives and integrals of functions and offers various commands.

The central theme of GeoGebra is an expression in the algebra window that corresponds to an object in the geometry window and vice versa!

Get doodling, then get serious

Constructions are simple enough; so is the entering of formulas. A first-timer can get used to it in no time: just click on three points in the window as shown above, and the points get defined. Then, in the formula window, just type in $A+B+C$ (where those three are the points), and you'll get the summation point D displayed in the geometry part of the window!

Help, of course, is provided in the form of a PDF file that's part of the installation, as well as comprehensive in-program help. GeoGebra is probably the ultimate freeware tool for learning and visualising basic mathematics.
