

Java applets on physics

There are links to 49 applets on this page, and if required, a student can download all of them for offline use, through the separate download link. The page and applets are a bit too garishly coloured, but the learning potential is not hindered in any respect due to this.

There are applets on the following topics: Mechanics, Oscillations and Waves, Electrodynamics, Optics, Thermodynamics, Theory of Relativity, Physics of Atoms, and Nuclear Physics. The range and depth of topics covered by the applets makes it clear that they are targeted at high school physics students. Topics like Ohm's Law, Wheatstone's Bridge, Refraction of light, etc., which form part of a high school curriculum are explained well with the applets. This would also probably explain the author's attempt at using vivid colours everywhere. The applets are accompanied by brief instructions on usage, and a very few of them also have a small description of the phenomenon being demonstrated. The applets are comparatively simple, with few changeable parameters making it easier for young students to use the applet without feeling overwhelmed by too many controls.

In conclusion, the applets on offer here are a great opportunity for students to brush up their lab activities without having to visit one. The few lapses in translation are the only drawbacks of the site, though they do not obscure the author's words.
