

These four numbers were generated by one click. It could have been four hundred

Line by line, here's what the code does:

1. The declaration that this is a “subroutine”—something that will be executed when it is called upon to do so.
2. Do the following for the values of x from 5 to 8.
3. Select the cells in row x and column 4, with x being dictated by whatever iteration of the loop the program is in.
4. Set the value of the cell to the square of the row number.
5. “Next x ” indicates the end of the loop.
6. End this subroutine.

You'll often be using the for... next loop in Excel, because many things need to be done repetitively across cells.

Now about help: say you see, in your macro, which you recognise by name, you see something like “ActiveCell”. You don't know what it does. Simply highlight it, and press [F1], and you'll get help—you'll see what “ActiveCell” means, in what contexts it's used, and so on.

Record various macros, look up the help in this manner, and you should get a hang of how to code in VBA—or at least modify your own macros.

On to modifying macros: if the macro you want to edit is in your Personal Macro Workbook, you need to un-hide the workbook. To un-hide the PMW, click the Unhide command button on
