

The above example is a list of books along with their categories and price. For the purposes of our totalling task, we are concerned with the book category and price, since we want to find the total price of the books in each category. Hence, the column that lists the category (column D) and the price (column E) become part of the range argument (D2:E58). In the example, we have extracted the totals for three categories of books: comics, thriller/mystery, and romance. These become part of the criteria argument. Finally, the price data we want Excel to total up lies in the E2 to E58 range. This we specify as the sum_range argument. Hence the formulas used to calculate the totals price of books in these categories will be:

```
=SUMIF(D2:E58,"=comics",E2:E58)
```

```
=SUMIF(D2:E58,"=Thriller/Mystery",E2:E58)
```

```
=SUMIF(D2:E58,"=romance",E2:E58)
```

The SUMIF function is great when you have just one criterion to work with, but what if you need to use multiple criteria? This is where the Conditional Sum Wizard comes in.

First you need to activate this Wizard from the Add-ins dialog box. To do that, open the Excel option for it by clicking on the Office Button and then on the Add-ins section. At the bottom of the window next to "Manage:", select Excel Add-in from the drop-down list and click "Go..." Check the "Conditional Sum Wizard" and click OK. Excel will add this Wizard to the Solutions group in the Formula tab. Click on it to start.

In the first step, the Wizard asks you to select the range which contains the
