

To perform validation of the data entry in a cell, select the cell first and then choose the Data Validation command. This can be found on the Data tab under the Data Tools group.

In the resulting pop-up, you will get an “Allow” drop-down list. This list contains the types of data that you can control for entries.

To control the validation on the data entry for the cell, select the data type first. The choices you have are: Whole Number, Decimal Number, List, Date, Time, Text Length, and Custom.

Data validation entries

If you choose Whole Number, Decimal Number, Date, Time, or Text Length, you have the further option to specify whether the data should be between, not between, equal to, not equal to, greater than, less than, greater than or equal to, and less than or equal to a maximum and minimum value. In such a case, any data that falls outside this range will result in an error warning if you give a customised error message in the Error Alert tab. You can also give a custom message on the Input Message tab which will be visible to users when they choose that particular cell.

If you choose the Custom data type you will have to specify a formula that will be used in validating the data entry. You will need to enter a formula that calculates the logical value **TRUE** or **FALSE**.

If you choose List you will need to specify a list on the same worksheet or a named range on another worksheet. To do this, first create a list on the same worksheet, or on another worksheet, and give it a name. Then click on the cell and choose Data Validation. Select the List option in the Source box, select the cell range in the same worksheet or enter the name of the range on
