

Interest) is $B1*B2$. We can use a Data Table to see how changes in Rate of Interest and/or Capital influences the interest amount.

Case 1: One-Variable Data Table

For this purpose we shall assume that the rate of interest is fixed at 10%. So cell B2 contains “10”.

We can list different capital amounts in Column A, in the cell range A5:A10. Excel dictates that the formula, in the case of a One-Variable Column Data Table, should be in a cell that is one column to the right and one row above the first value of the input column. In our case the formula should be in the cell B4.

	A	B
1		
2		=A2+1
3	3	=TABLE(,A2)
4	4	=TABLE(,A2)
5	5	=TABLE(,A2)
6	6	=TABLE(,A2)
7	7	=TABLE(,A2)

Formula location in a one-variable Column Data Table

Having ensured this, select the cell range A4:B10, consisting of the input values and the formula cell, and launch the Data Table tool by clicking on the Data Table Link. A window will pop up and ask for the “Row Input Cell” or “Column Input Cell.” Since our data is in columns—that is, we are dealing with a Column Data Table—the Column Input Cell needs to be mentioned. This will be the input factor which will be changed with the values in the column. In our case, since we are changing the Capital amount, the Column Input Cell is B1. Clicking on OK will populate the cells B5 to B10 with the different interest figures calculated by changing the Capital figures in A5 to A10.

In the above scenario, we could have used the cells B5:G5—that is, a row—to populate the different Capital amounts. In this case, the formula needs to be in the cell that is one row below and one column to the left of the first value in the input row. This means the formula has to be entered in the cell A6. The cell range A5:G6 has to be selected before launching the Data Table Tool. The Row Input Cell
