

Berkeley's UNIX was the first that included a library that supported the Internet Protocol. It was being used as the test-bed technology in various universities, free products, commercial products, and even in embedded systems. Under BSD licensing, companies were allowed to distribute proprietary software products without releasing the source code. It could be run Using a binary compatibility layer and native software of different OSes on the same architecture, and also, it was much simpler and faster.

The first BSD was like an add-on to UNIX' Sixth Edition, which had major new offerings such as a Pascal compiler and Joy's ex line editor.

A VAX computer got installed at Berkeley, but the UNIX/32V was unable to take advantage of the VAX's virtual memory. Berkeley students wrote the kernel of the 32V for enabling the use of virtual memory, and using the utilities from 32V, the third BSD was released towards the end of 1979. The third BSD is also known as VMUNIX (Virtual Memory Unix).

The credit of 3BSD's success goes to DARPA's funding of Berkeley's Computer Systems Research Group. This group would later develop a standard UNIX platform in the VLSI project for the DARPA research in the future. Post that, a number of BSD versions were released; the last was 4.4BSD. Many distributions have been developed and are available to use Based on 4.4BSD.

Colour Me Good

The Apple II's colour graphics was the major reason for its instant success when it was released in 1977. It carried a printed circuit board (PCB), keyboard, game paddles, A/C power cord, and cassette tape, with the computer game *Breakout*.

June: The Founding Of Oracle

Oracle was founded in California by Lawrence Joseph Ellison along with Robert Miner and Edward Oates. The company was initially formed by the name of Relational Software Inc. The first Relational
