

So there's only so much that Web statistics can tell us for sure:

- How many times a Web site is accessed from the same IP address in a particular duration of time
- The number of IP addresses that request data from a Web site
- When exactly each request is made
- The most popular URLs on a particular site
- The particular day of the week or the time of day that the server remains most active
- The geographical location of the servers that request access the maximum number of times.
- The kind of files that are most requested from a particular IP address (JPEG, HTML, etc.)

Ideally, calculating visits on a per-page visit is more reliable. The better log-analysis tools available in the market can rank pages on a Web site, showing which are most popular and which pages are rarely or never visited, enabling webmasters to modify the content accordingly.
