

you click on a group, all the bookmarks stored under it open in separate tabs at once. You also have the option of creating aliases for long URLs that you visit frequently—type ‘yahoo’ instead of ‘mail.yahoo.com’ to visit your Yahoo! Mail login page, for example.

An example of the URLs associated with the F1 key in Maxthon.

Let's create this alias in three easy steps now:

1. In the browser, go to Tools > Maxthon Setup Centre
2. In the new tab that opens click Navigation and scroll to URL Alias
3. You can now enter the alias name and the URL.

Apart from this functionality, you can also use the function keys to open a group of URLs, all you have to do is go to Tools > Maxthon Setup Centre > Navigation and scroll to URL Key. You can now select the function key you want to use along and enter the URL addresses you want to associate with that key.

The browser also has a small Notepad-like utility called Simple Collector that can be used to store URLs, text or images from sites, or to write JavaScript scripts and run them on the open Web page.

Another queer option in the browser is Split View. What this does is divide the browser into two columns, each with its own set of tabs. This is most useful when you're using a dual monitor setup. You can select a column by clicking into it and drag-drop tabs from one column to the other.

The Split View functionality in Maxthon
