

RGB images use three colours, or channels, to reproduce colours on the screen. The three channels translate to 24 (8 bits x 3 channels) bits of colour information per pixel. With 24-bit images, up to 16.7

RGB channels and their corresponding greyscale values

million colours can be reproduced. With 48-bit images (16 bits per channel), even more colours can be reproduced. In addition to being the default mode for new Photoshop images, the RGB model is used by computer monitors to display colours. This means that when working in colour modes other than RGB, such as CMYK, Photoshop interpolates the CMYK image to RGB for display on-screen.

Although RGB is a standard colour model, the exact range of colours represented can vary, depending on the application or display device. Photoshop's RGB Colour mode varies according to the working space setting that you have specified in the Colour Settings dialog box.

1.4.2. CMYK Colour Mode

In Photoshop's CMYK mode, each pixel is assigned a percentage value for each of the process inks. The lightest (highlight) colours are assigned small percentages of process ink colours, the darker (shadow) colours higher percentages. For example, a bright red might contain 2% cyan, 93% magenta, 90% yellow, and 0% black. In CMYK images, pure white is generated when all four components have values of 0%.

Use the CMYK mode when preparing an image to be printed using process colours. Converting an RGB image into CMYK creates a
