

- When you convert a colour image to multichannel, the new greyscale information is based on the colour values of the pixels in each channel.
- Converting a CMYK image to multichannel creates cyan, magenta, yellow and black spot channels.
- Converting an RGB image to multichannel creates cyan, magenta and yellow spot channels.
- Deleting a channel from an RGB, CMYK or Lab image automatically converts the image to Multichannel mode. (See About colour channels for more information on channels.)
- To export a multichannel image, save it in Photoshop DCS 2.0 format.

1.5. Hue, Saturation and Brightness

Hue, saturation and brightness are aspects of colour in the RGB scheme. These terms are most often used in reference to the colour of each pixel in a CRT display. All possible colours can be specified according to hue, saturation, and brightness (also called brilliance), just as colours can be represented in terms of the R, G and B components.

Most sources of visible light contain energy over a band of wavelengths. Hue is the wavelength within the visible-light spectrum at which the energy output from a source is greatest. This is shown as the peak of the curves in the accompanying graph of intensity versus wavelength. In this example, all three colours have the same hue, with a wavelength slightly longer than 500 nm, in the yellow-green portion of the spectrum.

Saturation is an expression for the relative bandwidth of the visible output from a light source. Saturation is represented by the steepness of the slopes of the curves. Here, the red curve represents
