

```
package samplecode
{
    public class SampleCoding
    {
        public var sampleGreeting:String;
        public function sampleFunction()
        {
            trace(sampleGreeting + " from
sampleFunction()");
        }
    }
}
```

The class that is declared above is the `SampleCoding` class lying inside the `samplecode` package. Due to this the compiler automatically assigns the class name during compile time into its qualified name.

2.7 Constructor Methods

In ActionScripting, the constructor methods are sometimes known as simply constructors or functions which share the same name as that of the class in which they are defined. A code that is included in a constructor method is executed whenever an instance of a class is formed with the help of the `new` keyword. This is explained below where a simple class is created containing a single property. The initial value of the property is always set inside the constructor function.

```
class Examples
{
    public var status:String;
    public function Example()
    {
        status = "initialized";
    }
}
```
