

- The colon operator (:)
- The Function class to indicate the data type
- The assignment operator (=)
- The function keyword
- The parameters, in a comma-delimited list enclosed in parentheses
- The function body—that is, the ActionScript code to be executed when the function is invoked, enclosed in curly braces

Consider the following code where a particular is declared using the function expression.

```
var tracePara:Function = function (aParam:String)
{
    trace(aParam);
};
tracePara("good morning"); // hello
```

It should be noticed that the function name need not be specified as in the case of a function statement. Besides this there is another major difference between function expressions and function statements — i.e a function expression is mainly an expression rather than a statement. This implies that any function expression does not have the capacity to stand on its own as is the case with a function statement. On the other hand a function expression can only be used as a part of a statement usually in the form of an assignment statement. This can be demonstrated by the below statement.

```
var tr1:Array = new Array();
tr1 = function (aParam:String)
{
    tr1(aParam);
};
tr1[0] ("hello");
```

In Flash ActionScripting, the function statements are more readable and allow the programmer to override the final key-
