

5.2 Methods

The word ‘method’ is synonymous to function and belongs to a part of the class definition. When an instance of the class gets created, a method gets bound to that interface. A function can be conveniently declared outside a class but on the other hand a method cannot be used apart from the instance to which it is attached. In general a method is defined using the function keyword. A function statement can also be used as shown below.

```
public function sample1():String {} // here sample1 is declared as a function
```

Besides this a variable can also be used to which a function expression can be assigned. This can be shown by the example given below.

```
public var sampleFun1:Function = function () {}  
// here sampleFun1 is used as a variable to which a function expression can be assigned
```

5.3 Modular Functions In ActionScript

In Flash ActionScripting, the concept of modular functions is widely used for developing various applications. One such application can be the falling of snowflakes. The user can take the help of the reusable modular function for creating this application.

Let us take an application where modular function is used. Consider the code given below:

```
function update()  
{  
  
    if (action == "run")  
    {  
        if (direction == "right")  
            this._x++;  
        else
```
