

```
# include <iostream.h>

int main()

{
float x, y;
float sum, ave;

cout<<"Enter two numbers: ";
cin>> x;
cin>> y;
sum = x+y;
ave = sum/2;
cout <<"Sum =" <<sum<<"\n";
cout<<"Average = " <<ave<<"\n";
return 0;
}
```

The output of the program is as follows:

```
Enter two numbers: 4 6
Sum = 10
Average = 5
```

After the `main()` function, two variables (`x` and `y`) are declared. The variables are declared as `float`, which is nothing but the data type. In the next statement, another set of `float` type variables '`sum`' and '`ave`' are declared. These two statements can be replaced by the following statement.

```
float x,y,sum,ave;
```

The statement following tells the user to enter two numbers. The `cin` identifier and `>>` operator (extraction operator that is used to get bytes from input stream class) then accepts two valid numbers via the keyboard. Next the values of the variables `x` and `y` are added and stored in variable '`sum`'. The variable '`ave`' is used to
