

<code>\"</code>	Double quote
<code>\'</code>	Single quote
<code>\0</code>	Null
<code>\\</code>	Backslash
<code>\v</code>	Vertical tab
<code>\a</code>	Alert
<code>\?</code>	Question mark
<code>\N</code>	Octal constant (where N is an octal constant)
<code>\xN</code>	Hexadecimal constant (where N is a hexadecimal constant)

Let us look at the example below:

25 represent decimal

0125 represent octal

0x125 represent hexadecimal

We can define our desired names for the commonly used constants by using the `#define` pre-processor directive. Let us look at the syntax of it:

```
#define identifier value
Now let us look at the example below:
#define NI 1.123456789
#define NEW '\n'
```

Here, the `'NI'` and `'NEW'` constants are defined. After defining these constants, we can use these in the remaining code just like any other regular constants.

```
// This is defined constants: determine the limits

#include <iostream.h>

#define NI 1.12345
```
