

```

        x+=3;                // this compound assignment
is equivalent to x=x+3
        cout << x;
        return 0;
    }

```

The output of this program is as follows:

7

● Increase (++) and decrease (--) Operator:

The increase operator (++) increases the value stored in a variable, while the decrease operator (--) performs the opposite.

● Relational and Equality operators:

While comparing two expressions, Relational and Equality Operators are used. Relational Operators always return a Boolean value (either True or False). The functions of various Relational and Equality Operators are as follows:

Operators	Function of the Operator
==	Equal to
!=	Not equal to
>	Greater than
<	Less than
>=	Greater than or equal to
<=	Less than or equal to

● Logical operators:

There are three types of Logical Operators: '!', '&&' and '||'. We use '!' in order to perform the 'NOT' Boolean operation. '&&' (AND) and the '||' (OR) operators are used to evaluate two expressions in order to get a single result.

'&&' returns 'TRUE' if both expressions are separated. If either of these expressions is false, then the operator returns 'FALSE'.
