

```
static void s1(void) // static member function
{
    cout<<"count: "<<y<<"\n";
}

};

int t1 :: y;

int main()
{
    t1 m1,m2;
    m1.set();
    m2.set();

    t1 :: s1();
    t1 m3;
    m3.set();

    m1.show();
    m2.show();
    m3.show();
    return 0;
}
```

The output of the program is as follows:

```
count: 2
object number: 1
object number: 2
object number: 3
```

Here, a class `t1` is declared. Two member variables `x` and `y` are declared. Here, `y` is the static member variable. The next three public methods to be declared are `set`, `show` and `s1`. `s1` is the static member function that displays the number of objects created till that moment. Similarly, the static member variable `y` main-
