

```
mn2.set(25);  
m1(mn2,mn1);  
return 0;  
}
```

The output of this program is:

25

Here, the function `m1()` has arguments from both the classes `MN2` and `MN1`. When the function `m1` is declared as a friend function in the class `MN2` for the first time, the compiler does not acknowledge the presence of the class `MN1`, unless we declare its name at the beginning of the program as `class MN1`; This is known as the 'forward declaration'.
