

Example:

```
<?php
print date("Y/m/d");
print "<br />";
print date("Y.M.D");
print "<br />";
print date("d-m-Y");
?>
```

The output of this code is as follows:

```
08/11/14
2008.Nov.Fri
14-11-08
```

A timestamp can be added in PHP date. In the date() function, the second parameter specifies the timestamp. Since this is an optional parameter, even if you do not supply a time stamp, the current time is automatically used.

Let us now discuss about the mktime() function. It is used to create a timestamp for the following day. The mktime() function returns the Unix timestamp for a particular date. The syntax is as follows:

```
mktime(hour,minute,second,month,day,year,is_dst)
```

Here all the arguments are integers.

To count a day in the future, add one to the day argument of mktime(). Look at the code below:

Example:

```
<?php
$nextweek =
mktime(0,0,0,date("m"),date("d")+7,date("Y"));
echo "Next ".date(1)." will be on ".date("d/m/Y",
$nextweek);
?>
```

The output of the above code is:

```
'Next Friday will be on 21/11/2008'.
```

Since date/time functions are the parts of PHP core, no installation is required to use this function.
