

The output of the above program is as follows:

The value of \$y is 11;

In the above example, the \$x and the \$y are the same variable with two different names. Therefore, increasing the value of \$x also affects the value of the variable.

Let's see how we can unset a reference:

While unsetting a reference, we need to separate the variable name from the variable content. Here, the variable content will not be ruined.

Example:

```
<?php
$x = 1;
$y =& $x;
unset ($x);
?>
```

Here, it will not unset the \$y variable, rather it will remove the association of the name \$x from the variable. The variable named \$y still holds the same Variable and has the same content.

The example given below will show how an object can be referred by other names.

Example:

```
<?php
class ourclass
{
    private $val;
    function getValue()
    {
        $this->val=10;
    }
    function showValue()
    {
        echo "within method value is ".$this->val;
    }
}
$ourObj = new ourclass();
$refObj = & $ourObj;
$refObj->getValue();
```
