

Example:

```
<?php
function __autoload($c_name) {
    print "Bad class name: $c_name!\n";
    include "abcclass.php";
}
$obj = new abc;
$obj->show();
?>
```

In the above example, we have tried to create an object of 'abc' class that is not defined previously. So the function `__autoload()` is called automatically by the PHP Engine. Inside this, we have included the File (abcclass.php) where the Class abc is defined. This will create the object as per our need.

__get()

The `__get()` function is used to specify the action if an unknown class variable is read from within the script.

Example:

```
<?php
class student{
    var $Name;
    var $roll;
    // public $address;
    public function __get($val) {
        print "Attempted to retrieve $val and
failed...\n";
    }
}
$std1 = new student;
print $std1->address;
?>
```

In the above example, the student class includes the commented declaration of the variable '\$address'. Here, the `__get()` function will be called to display the following output.

The output of the above program is as follows:

Attempted to retrieve address and failed...
