

3.2 Bypassing Keyloggers

A keylogger is basically spyware. As indicated by its namesake, it “logs” or records your keystrokes. When you type in your username or password, this information is logged and made available to the hacker. Keyloggers can either be physical or software-based, the latter being more difficult to detect.

A keylogger works in several different ways:

- Each keystroke is recorded and immediately dispatched to some remote listener over the internet.
- Keystrokes are collected in a temporary file, which is then periodically uploaded to the author's location over the internet.
- The keystrokes are collected in a temporary file, but much like a spam bot, can listen for and receive instructions from the author. The logger could thus upload the collected information when requested.
- The collected keystrokes could never be uploaded.
