

- Configure your wireless router.
- Connect your computers if there is an existent network or create a new one.

Choose your wireless equipment.

Choosing equipment is essential. As mentioned earlier, there are three different technologies: 802.11a, 802.11b and 802.11g. 802.11g is a safe bet, though if picky, any other should do. Check for range specifications. Also, if there is a likelihood of several devices operating in the spectrum range, choose something else.

Wireless Router

What you should have or what you need:

- Internet connection (only to create a network to access the net – for a small wireless area network, you do not need internet access).
- Wireless router.
- A computer with built-in wireless networking support or a wireless network adapter.

The router converts the signals coming across your internet connection into a wireless broadcast. A router is essential. Network adapters wirelessly connect your computer to your wireless router. You might not need this in case it is a newer computer. In case of a desktop, we recommend a USB wireless

Wi-fi USB stick

network adapter. In case of a laptop, a PC card-based one should do the trick. Make sure that you have one adapter for every computer on your network.

To make setup slightly easier, choose a network adapter made by the same vendor that made the router.
