

Sometimes fog appears like an inverted cone. The only difference between people who light on sets of a movie, television or a commercial is that they light the scene in the real world using spot lights, bulbs, bounce, diffusions, reflectors and overheads, whereas a 3D lighting artist does it in a 3D world with 3D lights and a set of attributes that are in one single software.

For a 3D lighting artist, being aware of the different lighting conditions is very important. To understand how the 3D lighting works, it's important to play around with the lights and get familiar with the term, and lighting itself. In Maya, if you don't have any lights in your scene, it will be rendered as a complete black image.

The types of lights that Maya has are Ambient, Directional, Point, Spot, Area and Volume light.

If you don't add lights to a given scene, the entire scene and objects will be rendered as a black frame (as in Maya). In other programs (such as 3DS Max), there is default lighting in a scene that is replaced as soon as you start adding lights. Depending on how you add lights to the scene will determine the effect.

Lighting guidelines

- The type of lighting you would use for your scene would depend on things like

In a scene during the night, notice the street light, you can see dust floating in the air

RimLight separates an object from the background

If a colour is a hot, it should come from a hot source such as a candle or sun. Similarly, cold colours from the sky, water or snow
