

button called “main menu” which takes him back to the original main menu view. To establish the above, start by creating a “View-Based Application” in Xcode and call it “Mview” for multiple views. As always open the MviewViewController.xib file in the interface builder. Add two “button views” to it and call them choice 1 and choice 2. Switch to Xcode and modify your MviewViewController.h as follows:

```
#import <UIKit/UIKit.h>

@interface MviewViewController : UIViewController {
}

//Following defines the action for both buttons.
-(IBAction) displayView1:(id) sender;
-(IBAction) displayView2:(id) sender;
@end
```

Back in Interface builder link the “Choice 1” and “Choice 2” button to the “File’s Owner” by dragging them. This will by default link the “touch up inside” event of the two buttons to the displayView: action created above.

Now in Xcode, right-click the classes group and add a new file. Choose the “UIViewController” subclass template. Here you will need to add the xib file explicitly since there is no option to auto generate it. Xib file can be added by right-clicking the resources group and then under the “User Interfaces” Group.

Available in the User Interface Group
