

5 Keyboard

iPhone is one of the few mobile devices that can display a usable QWERTY keypad in both the portrait and landscape orientation, courtesy its heavy width. The iPhone keyboard is also intelligent in the sense that it can automatically correct common spelling mistakes and like. In this chapter, we will learn to deal with keyboard, its variant and orientation. As a developer for the iPhone platform, you should be able to successfully summon the keyboard and make it disappear when you don't need it.

5.1 Input types

The keyboard is displayed by default, when you click any text field view. Now we will delve into the topic in further detail. To begin, open up Xcode and create a new View-Based application, let us name it kb. Open the auto generated kbViewController.xib file in the interface Builder. Add onto the view a Label and a Text Field.

Open the **tools > attribute inspector** for the TextField View that you have just added.

Pay special attention to the “Text Input Traits”, which gives you the following options

Capitalize: Auto capitalize the text that is entered, useful if you are requesting an alphanumeric serial in which all the alphabets are by default capitalised.

Correction: You can set it according to your wish. This will enable whether the keypad also gives suggestion regarding spelling to the user. So

You configure the handling of text
