

part mentioned above this, what lies next should be cake walk and rewarding too. In the same terminal session, or if you have closed your terminal than open it and go the same directory where you had extracted your source and issue the following

```
$ make
```

Mind you that for a large program this can be quite some time, for example during installation of Firefox, you can possibly finish your lunch with ease, of course setting the `CONCURRENCY_LEVEL` to the number of processors/cores you have to speed things up a little.

This has compiled your program, with the assumption you actually want to install it since you have done so much work, issue the following:

```
$ sudo checkinstall
```

The above is a replacement for `sudo make install` that might be there in some tutorial or in the readme. It is a better way, and it also puts it in your package manager so you can use synaptic to remove it. Also this creates a deb file so you can distribute it for your friends and earn brownie points.

Yes, we agree, this ain't for the faint hearted but trying out a few times will make the process far smoother than it looks currently.
