

```
<link rel="stylesheet" media="print" type="text/css" href="print.css" />
```

If a style sheet has a media type of screen, it will not be used when the page is printed. If no media type were specified, the style sheet would influence the printed result. Note also that any style sheet intended only for printing purposes must be given the print media type to prevent it from being implemented on screen. It is therefore very important to specify the media type correctly.

The next most popular media attribute is `media="handheld"`, which, while not supported by all mobile devices, is still in common use as browsers will ignore its content, allowing many cell phone or PDA users to access a stripped-down version of your styling depending upon support. Again, all that is required is another `<link>` element with `media="handheld"` specified, calling a specific style sheet such as `handheld.css` or `mobile.css`.

1.6.2 Multiple style sheets and the use of directories

As you keep increasing the number of rules used, your external style sheet will become really long and unmanageable. It is always recommended that you spilt your CSS into smaller chunks. Also, you might have separate style sheets for browsers, for print and for mobile devices if necessary. Soon you'll be looking at multiple style sheets for other reasons. The best approach to managing these is to use separate folders for each.

1.6.3 Modular CSS

An effective way of managing your CSS is dividing your CSS into modules, such as default key rules (font control, colour, headings) which apply to every page and some rules that will be applied to `<form>` elements used only on a few pages. You can create a specific style sheet for each module. For example, say a default module, forms module, navigation module, and so on. By combining each module, you will end up with the CSS for a complete site, yet everything remains separated, and you can navigate through them with ease.

In the following example, the basic style sheet (`external.css`) is used to import two modular ones (`default.css` and `layout.css`) to have a combined effect on the HTML:

1. Create a new style sheet called `default.css`.
2. Place the CSS `p {color: #red;}` in it and save the file.
