

}

```
/* Apply padding to heading to avoid Box Model woes */
h1 {
padding:0 0 0 10px;
}
```

The padding has also been removed from the masthead at this stage to keep things simple, and instead added to the h1 selector. (To find out why, skip to the section “The Box Model” later in this chapter.) The next step is to declare a right margin for the content ID as we did in the floated sidebar method earlier in the chapter. When the sidebar is positioned later, it will be slotted into the space created by this right margin.

```
/* Content */
#content {
margin-right:40%;
margin-bottom:10px;
padding:10px;
border:1px solid #000;
}
```

As mentioned, the sidebar now needs to be positioned into the space to the right of the content ID. It is very important when using positioning to be mindful of any extra issues that might flaw your positioning. In this example, note that there is 10 pixels of padding around the whole body element,

and that there is also a 10-pixel margin directly below the masthead. There is also a 1-pixel border around each edge. We need to add these measurements to the height of the masthead (60 pixels) in order to know exactly how far from the top of the browser window the sidebar needs to be. In this case, it's $10 + 1 + 60 + 1 + 10$, equaling 82 pixels from the top of the window.

```
/* Sidebar */
#sidebar {
position:absolute;
```

The sidebar overlaps the footer if it has more elements
