

rules in an external style sheet that is dictating the presentation across your web site, and for some reason, you need to overrule some of the external styles for just one of your pages, you use cascading. For that one particular web page, you could use the embedded CSS in the `<head>` of the page, redefining the appropriate rules there itself. When this particular web page is loaded in the browser, it will apply the embedded CSS instead of applying your external CSS for the defined rules. Any identical selectors in the external style sheet will be ignored. Similarly one step up in the hierarchy is the inline styles. Whatever styles you apply inline will overrule any declarations in the `<head>` of the page or an external style sheet.

To see this in action, you can run through the following example:

1. Open `external.css` and define the default paragraph colour with `p {color: #red;}` and save the file.
2. View `external.html` in your browser. Assuming you are still applying CSS using `external.css`, any default paragraphs should be red.
3. Now open `external.html` and apply the embedded style `<style type="text/css">p {color: #333;}</style>` in the head of the template.
4. Reload `external.html` in your browser. Now any default paragraphs should be dark gray, as the embedded CSS is overriding the linked style sheet.
5. Finally, find a default paragraph in `external.html` and define it with an inline style, such as `<p style="color: #CCC">` and save the template.
6. Reload `external.html` in your browser. Now the paragraph to which you applied the inline style should be light gray, as the inline CSS is overriding the embedded CSS and the linked style sheet. Any other default paragraphs should still be dark gray based on the embedded style. Another method of using the cascade is in the form of multiple external style sheets.

You have already seen how to link to one or more external style sheets for various platforms (such as printers and mobile devices), and this approach is similar, except all the external files here are specifically for the screen:

```
<link rel="stylesheet" media="screen" type="text/css"
href="css/screen/one.css" />
<link rel="stylesheet" media="screen" type="text/css"
href="css/screen/two.css" />
<link rel="stylesheet" media="screen" type="text/css"
href="css/screen/three.css" />
```
