

Now all the emphasised text across the site is rendered in red, and the element no longer inherits its colour from the parent element. Unless otherwise defined in your `em` selector, other declarations will still be inherited from the parent.

It is strongly recommended that all major CSS design implementations begin with a `<body>` element declaration in the main style sheet. The `<body>` element is the parent of every visible element in your template, and therefore every element without a specified rule inherits from it.

```
<body>
<h1>Absolutely everything else!</h1>
<p>Yep, every visible element is contained within the
body.</p>
<p>And so on.</p>
</body>
```

For example:

```
/* Define all main values for the web site */
body {
margin:10px;
font-family:Helvetica,Arial,sans-serif;
background:#CCC;
color:#000;
}
```

As a result of these declarations, every other rule in the CSS will inherit the values unless specified otherwise. So all headers, paragraphs, lists, and other elements will be rendered with black text (`color: #000`) using the first available font from the suggested options on the end user's machine (`font-family: Helvetica, Arial, sans-serif;`) unless the selector for each child element specifies otherwise, or that child element is housed inside a more immediate parent (such as a column or container) that contradicts the inherited values from `body`.

Note that some style properties are not inherited from the parent element, the background property being the main example. The child element does not actually inherit the light grey background (`background: #CCC;`), but rather the parent element's background appears by default. In other words, the child element can be thought of as
