

```
padding:0 0 0 25px;
width:200px;
list-style-image:url(images/list.gif);
}
```

As `list-style-image` is declared, there is no need to specify `list-style-type`. Note also that the left padding has been increased to compensate for the width of the image. The wider your custom bullet image, the more left padding you may need.

List properties can also be shortened into one declaration, using the `list-style` property. The order is `list-style-type`, `list-style-position`, `list-style-image`. `list-style: none inside url(images/list.gif);` However, it is not often that you would need to specify all three properties. In this example, declaring a custom image with `list-style-image: url(images/tile.gif)` removes the need to also turn off the basic list marker, except in the shorthand. Therefore, just specifying a custom image will be all you need in most scenarios.

Using the `list-style-image` property is the easiest method of assigning a custom bullet to your list items, but the results can be somewhat inconsistent. Some browsers will align the custom image directly in the middle of the list item text, while others will position it slightly higher. To beat this problem, a custom background image can be used for each list item. Note that default bulleting is turned off in the `ul` selector.

```
ul {
list-style:none;
```

Here the list markers are actually background images

```
}
li {
background: transparent url(images/list.gif) no-repeat
left center;
padding:0 0 0 25px;
```
