

are underlined.

The next step is to define any shared declarations for links within the unordered list. For this example, let's turn off all underlines. If you decide that perhaps you'd like underlines on the hover state, simply remove the `ul a:hover` selector from the grouping. Very importantly, the padding declaration must be removed from the `li` selector and placed instead in the grouped values for the pseudo classes. This is because the whole list element needs to be a clickable link, so by adding that padding in the pseudo classes, the active area is not merely the link text, but is increased to the whole link element. Finally here, `display:block` is added. This ensures that the active link area is the whole width of the link element. This means that one can follow the link by clicking anywhere in the list element, not just by clicking the link text.

```
ul a:link, ul a:visited, ul a:hover, ul a:active {  
  display:block;  
  padding:2px 10px;  
  text-decoration:none;  
}
```

Next, unique selectors can be added to assign specific declarations for each link state. Note that again the selector descends through `ul` and `a` before the pseudo class is stated, ensuring the rules are targeted and will not affect links elsewhere in the page.

Visual changes can be observed when clicking the links

```
ul a:link {  
  color:#000;  
}
```

```
ul a:visited {  
  color:#666;  
}
```
