

Immediately after the `<p>` element, add the spacer `<div>` element. This horrible element is unquestionably presentational, but unavoidably necessary to force the container to stretch vertically to hold the image. The next step is to define CSS rules for the spacer:

```
.spacer {  
clear:left;  
}
```

By giving `clear` a value of `left`, the spacer is moved below the bottom outer edge of both the image float element and the paragraph. Although the spacer is invisible in the final result, it is now forcing the container to expand vertically to contain it.

Clearing the float is necessary in most similar situations, as it may be unknown as to how much paragraph text is to flow around the floated element. If more paragraph text were added so that it extends beyond the height of the floated image, the spacer would not be necessary, as the container would expand to contain the paragraph. Still, to be on the safe side, it is worth adding the spacer should the text be decreased at a later date.

8.3 Handling multiple floats

It makes sense to add more profiles underneath, within the main container. Without the use of spacer `<div>`s, things aren't quite right. The level 3 heading is correctly wrapping around my floated image. The first approach here might be to add a spacer `<div>` after each profile, as follows:

```
<h3>Judas Priest</h3>  
<div class="image_float"></div>  
<p>Can't actually play any instruments, and is just along  
for the ride supposedly as manager.</p>  
<div class="spacer"></div>  
<h3>Jimi Hendrix</h3>  
<div class="image_float"></div>  
<p>Possibly the greatest guitarist who ever walked the  
earth, Mr. Hendrix is thankfully alive once more to play  
the next <em>Dead Goods</em> tour across the North of  
England.</p>  
<div class="spacer"></div>
```
