

on most of the platforms including Linux, Unix and Windows. MySQL is also much faster and more robust than MS SQL.

ASP.NET uses MS SQL for storing and modifying data. Data access to MS SQL servers is provided by ADO.NET, which is a set of computer software components used for providing continuous access to data. MS SQL is created by Microsoft. It is proprietary and expensive. Weighing IIS against Apache, the results are similar to that of MS SQL and MySQL. Microsoft designed IIS, while the open source product here is Apache. The expression open source alternative is so frequently used that it feels the open source product is just an alternative and not as good as the supposedly “real” proprietary product. This is not necessarily true. It is open source hence cheaper and more easily available.

Apache is robust, reliable, secure and easily configurable on so many levels. Apache is available on Linux, Unix and Windows, but IIS will work well only with Windows as it is proprietary software. Apache runs projects that are Java-based. Java Database Connectivity works well on Apache. JDBC is an API for accessing tabular data sources from within Java code. It also provides cross-DBMS connectivity to a wide range of SQL databases and access to other tabular data sources such as spreadsheets or flat files. It also supports a wide variety of plug-ins for content management, application management and document presentation. Plug-ins are software modules that lets you view a document, interact with an image, listen to music or watch a video.

Apache is the most widely used Web server software package in the world. It is a multi-platform support. It runs on almost every platform out there. It can be used on systems with Intel x86-series processors running either Linux or NT as an OS, or on other computers running a Unix-type OS on a different processor. Apache with Linux runs faster than IIS with Windows. The reason being former does not require GUI (Graphical User Interface) instead it uses commands. If your customer is experienced in Linux, then you must recommend it because Linux is rather secure.

Nevertheless, it becomes very easy to use GUI, and, IIS with Windows gives you the option of using tools and integrating them with Microsoft products. However, Apache's developers do not provide any type of support for their products. Nonetheless, you can charge for the support you provide your customer.

IIS also has its share of advantages. It provides protection against crashes. Even if one application on the server crashes, the web server and other applications continue to run, and the failed application restarts the next time a user requests for it. It also limits bandwidth. Unlike other server software, IIS has the ability to limit how much bandwidth your web pages should use. It is closed source so it might cost him some
