

LEVEL 1 Datacenter Security

Our global datacenter partnerships are a result of a comprehensive Due diligence process. Security and stability are two of the most important variables in our due diligence process. All datacenters are equipped with surveillance cameras, biometric locks, authorization-based access policies, limited datacenter access, security personnel, and similar standard security equipment, processes and operations. What separates us however is the fact that our due diligence process also incorporates a measure of proactiveness demonstrated by the datacenter towards security. This is measured by evaluating past incidents, customer case studies, and the amount of time the datacenter dedicated towards security research and study.

LEVEL 2 Network Security

Our global infrastructure deployments incorporate DDoS mitigation, Intrusion Detection systems, and Firewalls both at the edge and the back level. Our deployments have weathered frequent hacking and DDoS attempts (sometimes as many as 3 in a single day) without any degradation.

Protection against Distributed Denial-of-Service (DDoS) Attacks

Denial of Service is currently the top source of financial loss due to cybercrime. The goal of a Denial-of-Service attack is to disrupt your business activities by stopping the operation of your web site, email or web applications. This is achieved by attacking the servers or network that host these services and overloading the key resources such as bandwidth, CPU and memory. The typical motives behind such attacks are extortion, bragging rights, political statements, damaging competition etc. Virtually any organization that connects to the Internet is vulnerable to these attacks. The business impact of large sustained DDoS attacks is colossal, as it would lead to lost profits, customer dissatisfaction, productivity loss and due to unavailability or deterioration of service. A DDoS attack in most cases would even land you with the largest bandwidth coverage invoice that you have ever seen.

Our Distributed Denial-of-Service protection system provides unrivaled protection against DDoS and DDoS attacks on your internet-facing infrastructures i.e. your websites, email and mission critical web applications, by using sophisticated state-of-the-art technology which automatically triggers itself as soon as an attack is launched. The DDoS mitigation's filtering system blocks almost all fraudulent traffic and ensures that legitimate traffic is

Be sure you verify how they assure your site's safety

could consider a .co domain. These are suggestions that you need to present in order to give your prospective client a larger bouquet of services. A business that has “company” in its brand would certainly prefer a .co TLD. So an “Ambar & Co.” would prefer an ambar.co to an ambar.co.in or ambar.net.in or such TLDs. Choice is something that is possible only with options. You present options, give your client a wider choice and he'll certainly be pleased with you! That's the key to a more rewarding business. Periodically, there are offers on newer TLDs by most service providers.

You will be able to offer such services to your clients only if you receive them, in turn, from your service provider. Now that you know what you need in a web site, you need to ensure that you are able to deliver on all counts. Also, another offer worth mentioning is that during the launch of domains, providers generally offer discounts. During the initial phase, before the domain has received the attention it so desperately desires, domain registrants sometimes offer it for real cheap. So a domain costing Rs.500 in the long run could be yours for Rs.100 or 200 if you got it early.
