

```
}
```

The for loop

```
for (initial condition; logical expression; change
loop counter variable) {
    ...statements...
}
```

Set the initial condition, then while the logical expression is true execute the statement between the braces while changing the loop counter as specified once at the end of each loop. This code segment is functionally equivalent to the one for the "while" loop.

```
for (a=0; a<10; a=a+2) {
    ...statements...
}
```

The case...switch construct

Case..switch is used in place of a series of "if...else" clauses when a variable can take on several values. The "default" clause at the bottom takes care of any cases not covered explicitly.

```
switch (variable) {
    case val1: ...statements 1...
    break;
    case val2: ...statements 2...
    break;
    case val3: ...statements 3...
    break;
    default: ...statements default...
    break;
}
```

4.2.10 PRE-PROCESSOR

Pre-processor directives all begin with a # and are followed by a specific command. Syntax is dependent on the command. Many commands do not allow other syntactical elements on the remainder of the line. A table of commands and a description is listed on the below:
