

alignment of your JLabel text within the label. By default, text is placed to the right of an image, an image is centered and text alone is left-justified. You can use HTML to specify the text of a label, and thereby get a more specific appearance. You can also set up tool tips, i.e.:

```
myLabel.setToolTipText( "Display This" );
```

Because this `setToolTipText()` method is inherited from class `JComponent`, then any descendants of `JComponent` also have this method !

This is how you would place an icon on the JLabel after it was already instantiated:

```
myLabel.setIcon( myIcon );
```

Set alignment:

```
myLabel.setHorizontalAlignment( CENTER );
```

You don't need to repaint the label after you change the alignment, because the change triggers a `repaint()`.

```
myLabel.setIconTextGap( intGap );
```

Integer values allow you set the gap between text and image.

This is an example of a JLabel that display an Icon, and that has had its state enabled and disabled:

Also, you can make the label have a different icon only when it is disabled by:

```
lbl.disabledIcon( Icon icon )
```

10.4 JTextField

Swing provides two distinct types of text components:

Simple text controls that can only display one font, and one color at a time:

`JTextField`, `JTextArea`, `JPasswordField`

Styled text components that can display multiple fonts, and multiple colors:

`JEditorPane`, `JTextPane`

`JTextField` uses the `ActionListener` interface to respond to events. When a `JTextField` fires an action event, the event's `actionCommand` is set to the text field's `actionCommand` property. Using the `JTextField`'s `setActionCommand()` method, you can explicitly set this property. Otherwise, it defaults to the contents of the `JTextField`. By default pressing the ENTER key while a `JTextField` has focus fires an Action Event. You set the Preferred Width by instantiating it with a number of columns, but the Layout Manager has the final say. The columns you set are assumed to be the letter "m", because it's the widest.
